

Social Welfare

Bruno Salcedo

Economics 2261 · Intermediate Micro II · Winter 2020

social welfare functions

How to choose a **public policy**, that affects **different individuals** with (typically) **different preferences** over policies?

- Harmonized Sales Tax rate
- Free trade agreements
- Ticket sales
- Display of news on social media
- Net neutrality
- Roads or bike lanes
- Ontario Hydro
- Consumption and production

A social choice problem consists of

- A set \mathcal{A} of alternatives A
- A set of individuals i
- For each individual i , a preference ranking \succ_i over alternatives

social welfare functions

We are after a social ranking \succ^* over alternatives

- Principle for deciding which outcomes are “good for society”
- Should depend on the preferences of the individuals

A **social welfare function** is a mathematical function that takes as input a list of preferences $(\succ_1, \succ_2, \dots, \succ_n)$ and produces as output a single preference ranking \succ^*

examples of SWFs

- Majority rule with two alternatives and an odd number of individuals
- Sequential plurality (top choice for most individuals) ▷
- Condorcet criterion (winners of pairwise elections) ▷
- Borda criterion (point-system voting) ▷
- Utilitarian (maximize sum of utilities)
- Rawlsian (maximize the utility of the worst-off individual)

arrow's theorem

What are some **minimal** properties a SWF should satisfy?

A SWF satisfies **universal domain** (UD) if every possible preference list results in a well defined social-ranking output

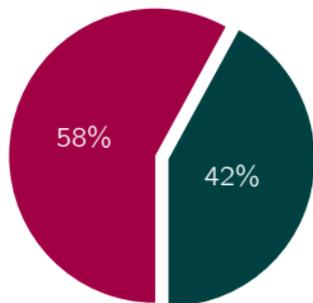

example of failure of UD

- The Condorcet criterion fails UD
- Consider the following example

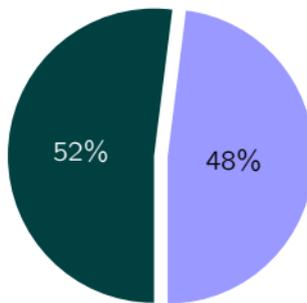

1	2	3
A	B	C
B	C	A
C	A	B

- According to the Condorcet criterion, $B \succ^* C$, $C \succ^* A$, and $A \succ^* B$
- How do we choose an alternative from \mathcal{A} ?

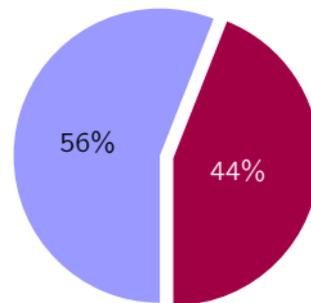

Condorcet cycle

May deal γ^* no deal

no deal γ^* remain

remain γ^* May deal

Thinking about your view of Brexit, for each of the following please say if it would be your first preference, second preference, or third preference.

What are some **minimal** properties a SWF should satisfy?

A SWF satisfies **unanimity** (U) if, whenever it happens that for some pair of alternatives A and B , every individual i ranks $A \succ_i B$, the corresponding social ranking also ranks $A \succ^* B$

independence of irrelevant alternatives

What are some **minimal** properties a SWF should satisfy?

A SWF satisfies **independence of irrelevant alternatives** (IIA) if, if the social ranking of A versus B depends **only** on the individuals' rankings of those two alternatives

example of failure of IIA

- The sequential plurality rule fails IIA
- Consider the following example

1	2	3	4	5	6	7	8	9
A	A	A	A	B	B	B	B	B
B	B	B	B	C	C	C	A	A
C	C	C	C	A	A	A	C	C

- According to the sequential plurality rule, $B \succ^* A$

example of failure of IIA

- The sequential plurality rule fails IIA
- If the preference of individuals 8 and 9 changes as follows

1	2	3	4	5	6	7	8	9
A	A	A	A	B	B	B	C	C
B	B	B	B	C	C	C	B	B
C	C	C	C	A	A	A	A	A

- Now, $A \succ^* B$

minimal properties a SWF should satisfy

- We have argued a good SWF should *at least* satisfy UD, U, and IIA
- These are **minimal** requirements
- They say nothing about equity, fairness, or how to conciliate conflict
- A good SWF should satisfy these, and probably some more requirements
- Is there any such SWF?

A SWF is a **dictatorship** if there exists some individual i such that the social ranking \succ^* is **always** exactly the same as \succ_i , regardless of the preferences of other individuals

Dictatorships satisfy our minimal requirements

- UD because there is always an answer ($\succ^* = \succ_i$)
- U because if A is unanimously better to B , then $A \succ_i B$, and thus $A \succ^* B$
- IIA because the social ranking of alternatives A and B only depends on the dictator's individual ranking of A and B

what else satisfies requirements?

- Simple majority fails UD
- Condorcet criterion fails UD
- Sequential plurality fails IIA
- Borda rule? (homework)

Arrow's impossibility theorem — If a SWF satisfies U, UD, and IIA, then it is dictatorial

what do we do now?

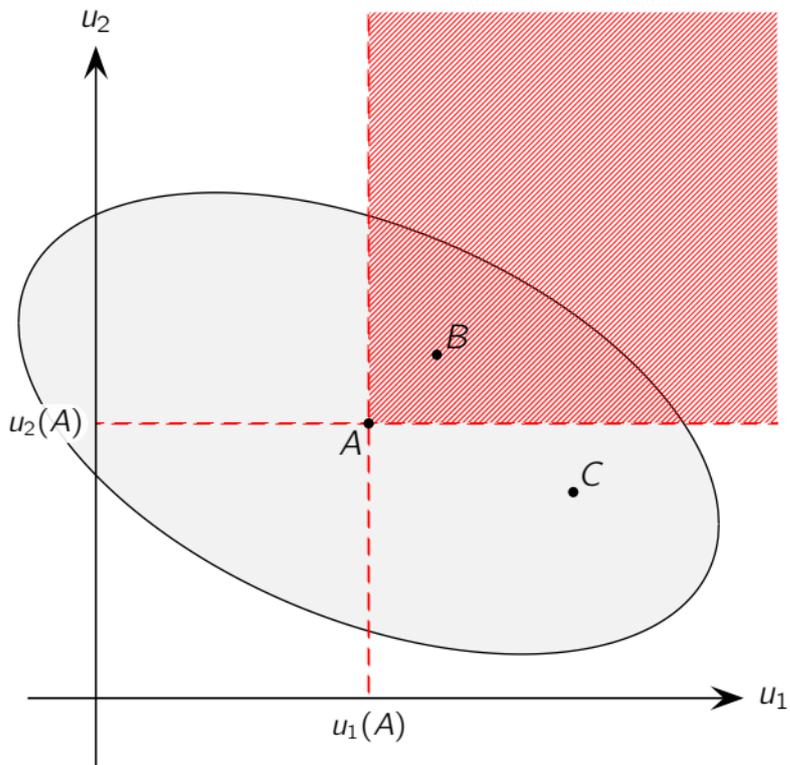

- Relax some of the “minimal” requirements? Which?
 - U is an important requirement we would **not** want to drop
 - IIA? Maybe...
 - Restricted domains? **Yes, in this course**
- More information? If we could measure utility we could use
 - Utilitarian (maximize sum of utilities) ▶
 - Rawlsian (maximize the utility of the worst-off individual) ▶
- Unfortunately we cannot measure utility **in general domains**

unanimity and efficiency

Alternative A **Pareto dominates** alternative B if **every** individual prefers A to B , i.e., $A \succ_i B$ for every individual i

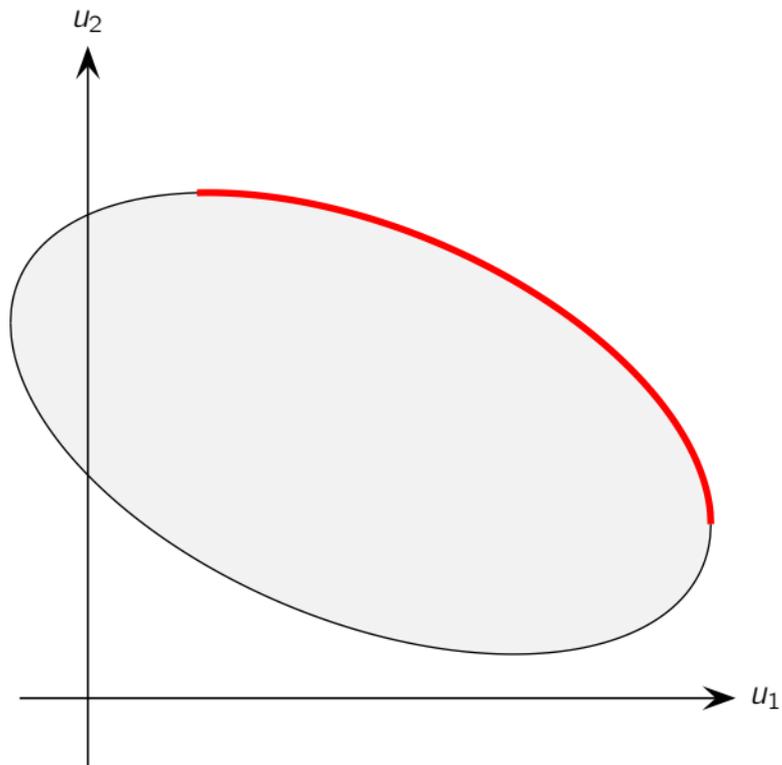

- Pareto dominance is a SWF designed around unanimity
- It satisfies U and IIA, but it fails UD
- In many cases, it yields **incomplete** rankings
 - Who gets the last ticket?
 - Public school assignment
 - Introducing Uber

alternative A is Pareto dominated by B but not by C

An alternative A is **Pareto efficient** if there is no other alternative that Pareto dominates it

- Compelling prescription — should **not** choose any alternative which is Pareto dominated, when it is feasible to choose an alternative that Pareto dominates it
- Fundamental principle of economics, often misused
- Not every Pareto efficient alternative dominates every alternative which is not Pareto efficient
- Better to think in terms of **Pareto improvements**

the set of Pareto efficient alternatives corresponds to the **Pareto Frontier**

willingness to pay

How large do we have to make the pile before you take the money?

Pareto efficiency with money

- Suppose there is one ticket and two people without tickets left
- Anna's willingness to pay is \$200
- Bob's willingness to pay is \$100
- What are the implications of Pareto efficiency?
- Give the ticket to the individual with the highest willingness to pay

restricted domain

monetary transfers

monetary transfers

- Suppose monetary transfers are possible and can be enforced
- A monetary transfer scheme can be represented by numbers t_1, t_2, \dots, t_n
 - t_i represents the amount **paid** by individual i (could be negative)
 - $\sum_i t_i$ is the total surplus (or deficit)
 - $\sum_i t_i = 0$ means that the scheme is budget balanced

quasilinear preferences

- Restricted domain of preferences that can be represented as follows
- Individual i 's **value** for alternative A is $v_i(A)$
- Individual i 's **utility** for alternative A and transfer t_i is

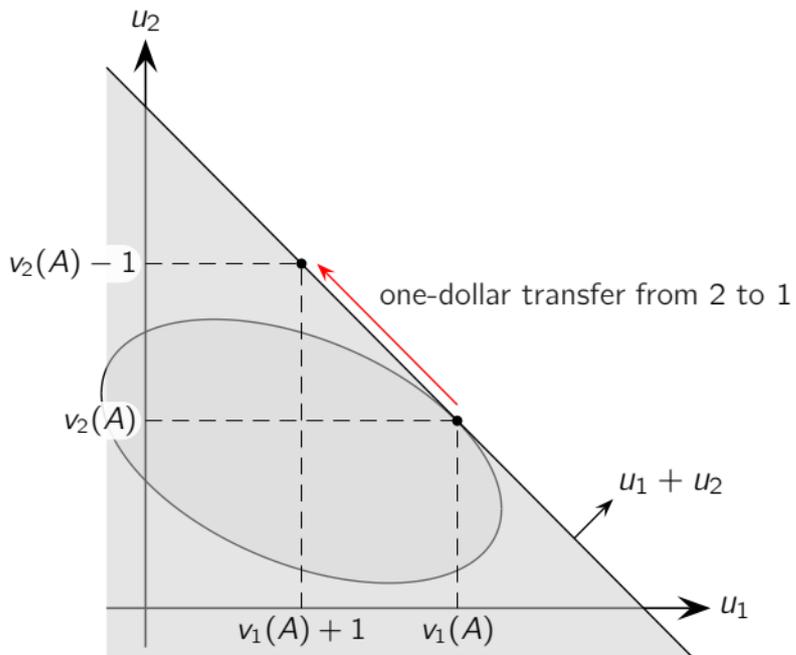

$$u_i(a, t_i) = v_i(a) - t_i$$

- The difference $v_i(a) - v_i(b)$ captures i 's willingness to pay for having alternative A instead of alternative B
- How restrictive is this domain?

If transfers are possible and all agents have quasilinear preferences, then (A, t) is Pareto efficient if and only if

$$\sum_i v_i(A) \geq \sum_i v_i(B)$$

for every other alternative B in \mathcal{A}

now the Pareto frontier is a line with slope -1

specific SWFs

appendix

sequential plurality

- The alternative with the most “top choice votes” is at the top of the social ranking
- Remove that alternative from the individual rankings, leaving the rest intact
- With the new individual rankings, find the alternative among those that remain with the most “top choice votes”
- That alternative is placed second in the social ranking
- Continue until all alternatives are ranked

sequential plurality example

1	2	3	4	5
A	A	B	B	B
B	C	A	A	C
C	B	C	C	A

- B has the most “top choice votes”
- Thus $B \succ^* A$ and $B \succ^* C$
- Once B is removed, A has more “top choice votes” than C
- Thus $A \succ^* C$

Condorcet criterion

- For each pair of alternatives A and B , count how many individuals prefer A to B and vice versa
- If more individuals prefer A to B , then A is socially preferred to B
- For the following example, following the Condorcet criterion yields $A \sim^* B$, $B \succ^* C$, and $A \succ^* C$

1	2	3	4
A	A	B	B
B	C	A	A
C	B	C	C

Condorcet vs. plurality

1	2	3	4	5	6	7
L	L	L	C	C	R	R
C	C	C	L	R	C	C
R	R	R	R	L	L	L

- Plurality rule — $L \succ^* C \succ^* R$
- Condorcet criterion — $C \succ^* L \succ^* R$

- Suppose there are n alternatives
- For each individual i assign points to alternatives as follows
 - i 's most preferred alternative gets n points
 - i 's second most preferred alternative gets $n - 1$
 - \vdots
 - i 's least preferred alternative gets 1 point
- Rank alternatives according to the total number of points assigned to them

Borda criterion example

1	2	3	4
A	A	B	B
B	C	A	A
C	B	C	C

preferences

	1	2	3	4	total
A	3	3	2	2	10
B	2	1	3	3	9
C	1	2	1	1	5

points assigned

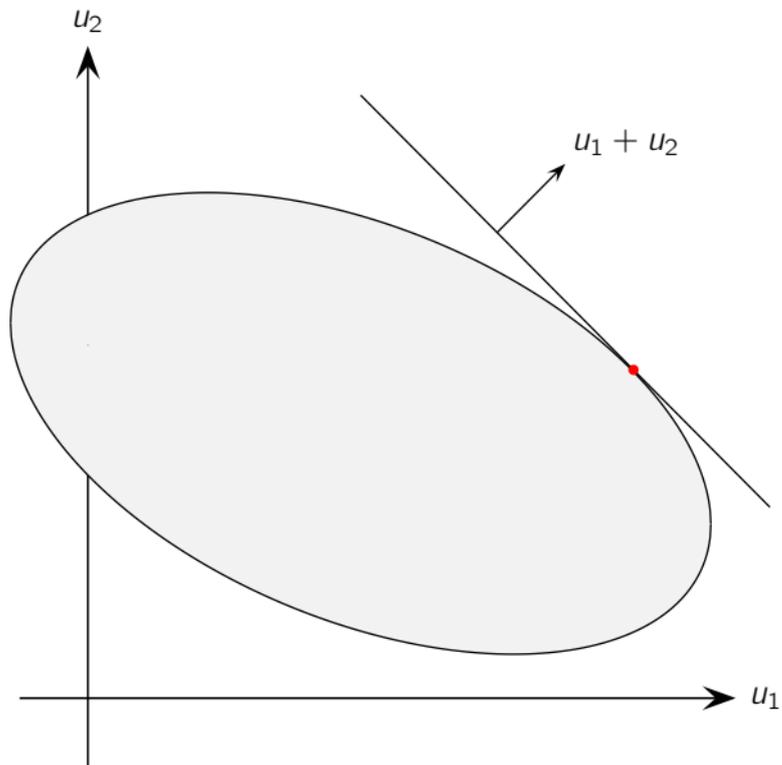

mill and rawls

appendix

- Suppose that we can **measure** utility
- For each individual i we have a utility function u_i over alternatives
- Utilitarianism says alternative A is socially preferred to alternative B if it generates more total utility for society

$$\sum_i u_i(A) > \sum_i u_i(B)$$

- Satisfies UD, IIA and U
- Susceptible to changes of scale (depends on cardinal information)
- Assumes same scale can be used to compare utility across individuals

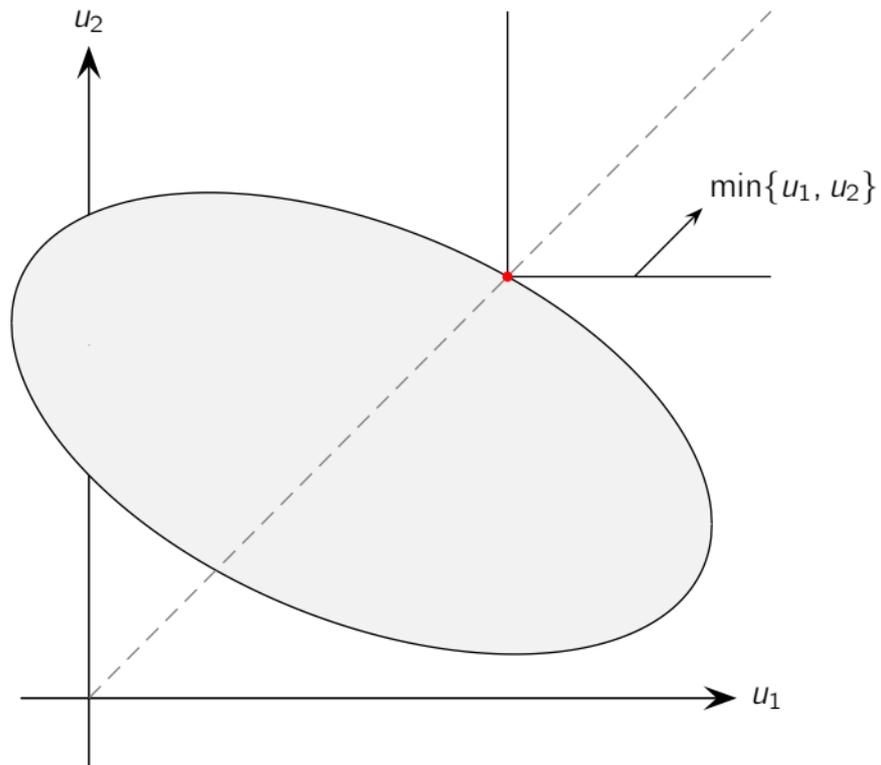

mill – people are treated like perfect substitutes

- Suppose that we can **measure** utility
- For each individual i we have a utility function u_i over alternatives
- Rawls says alternative A is socially preferred to alternative B if the worse off individual under A is better off than the worse off individual under B

$$\min_i u_i(A) > \min_i u_i(B)$$

- **Veil of ignorance** — what would individuals prefer before they knew their place in society?
- Satisfies UD, IIA and U
- Susceptible to changes of scale (depends on cardinal information)
- Assumes same scale can be used to compare utility across individuals

rawls – people are treated like perfect complements
